Background	function:Variant histone H2A which replaces
	conventional H2A in a subset of nucleosomes.
	Nucleosomes wrap and compact DNA into
	chromatin, limiting DNA accessibility to the cellular
	machineries which require DNA as a template.
	Histones thereby play a central role in transcription
	regulation, DNA repair, DNA replication and
	chromosomal stability. DNA accessibility is regulated
	via a complex set of post-translational modifications

of histones, also called histone code, and nucleosome remodeling. May be involved in the formation of constitutive heterochromatin. May be required for chromosome segregation during cell division., mass spectrometry: Monoisotopic, not modified PubMed:16457589,PTM:Acetylated on Lys-5, Lys-8 and Lys-12 during interphase. Acetylation disappears at mitosis., PTM: Monoubiquitination of Lys-122 gives a specific tag for epigenetic transcriptional repression.,PTM:Not phosphorylated., similarity: Belongs to the histone H2A family., subunit: The nucleosome is a histone octamer containing two molecules each of H2A, H2B, H3 and H4 assembled in one H3-H4 heterotetramer and two H2A-H2B heterodimers. The octamer wraps approximately 147 bp of DNA. H2A or its variant H2AFZ forms an heterodimer with H2B. H2AFZ interacts with INCENP.,
